

Migration Flight Recorder

Evidence before database change.

01 / PROBLEM

Database migrations can pass syntax checks yet fail on real data, break dependencies or remove valuable information. Developers need reproducible evidence before changing a database, not an unverified safety verdict.

02 / WHAT THE AGENT REACHES

Users submit SQL in TrueForge. The agent discovers PostgreSQL schema and data through read-only queries, identifies compatibility risks, and proposes explicit checks. With approval, it rehearses the exact SQL on a fresh Docker clone and reports statement outcomes, schema/data changes and verification results.

03 / WHERE IT STOPS

Separate native approvals precede rehearsal, backup preparation and local-target application. Missing evidence, blockers, denial, unsupported SQL, drift or expiry stop progression. Supported local plans use transactions and an audit ledger. The agent never approves itself; this is not a production migration service.

Decisions and execution

TrueForge provides chat, orchestration, session traces and native tool approvals. Crystal DBA supplies inspection; custom MCP services enforce bounded rehearsal and reviewed local execution.

KNOWN LIMITS

Reliability is incomplete: model-generated SQL and expected results can be wrong. Rehearsal supports one allowlisted PostgreSQL demo database, up to 1 GiB, with a conservative execution subset. Stronger authentication, authorization, secret isolation, independent security review and recovery controls are required before broader use. Clone success does not establish production safety.
